

Discovery - Bonus

Credential-less Discovery

If the instance fails to identify a configuration item (CI) because of authentication failure, Discovery or Service Mapping can run selected Network Mapper (Nmap) commands with a MID Server to collect some basic information about the CI without using credentials.

What Nmap can discover?

The Nmap commands executed during credential-less Discovery can:

- 1 - Identify the host from the IPv4 address.
- 2 - Return the MAC address of the host.
- 3 - Detect applications installed on a target host.
- 4 - Detect the operating system of a target host and the OS version.

Discovery - Bonus

Credential affinity

When Discovery runs for a device for first time, it checks all available credentials for the device. Once correct credential gets identified, a record is created in Credential Affinity table (**dscy_credentials_affinity**) to create affinity(connection) between device and credential.

So next time when discovery runs for that device, Credential Affinity table will be checked for the credential.
