

Service Mapping

(Top Down Discovery)

Service Mapping enables organizations to have a complete understanding of their IT infrastructure, making it easier to troubleshoot problems and ensure that services are delivered efficiently

An application service is a set of interconnected applications and hosts which are configured to offer a service to the organization. Eg: organization website.

Service Mapping relies on Discovery and the MID Server to discover devices and applications. Service Mapping uses results of horizontal discovery performed by Discovery.

Service Mapping - Flow

ServiceNow

Service Mapping Example

- We have configured one web application (ITSM) in our windows machine(10.0.0.4).
- This Web Application is hosted on Apache Tomcat Web Server and having connection with MySQL database (Path - ***C:\Program Files (x86)\Apache Software Foundation\Tomcat 9.0\webapps\ITSM*** .
- We can open this application on browser with URL (*http://10.0.0.4:8080/ITSM* or *http://localhost:8080/ITSM*)
- We run the discovery on IP 10.0.0.4 which will discover Windows Server, Tomcat, MySQL server.
- We will create this Application Service using Application Entry Point ***http://10.0.0.4:8080/ITSM*** in ServiceNow Instance.

Service Mapping - Pre-Requisites

Requesting Service
Mapping

activate ***com.snc.service-mapping***
plugin

Provide Roles to
Manage Service
Mapping

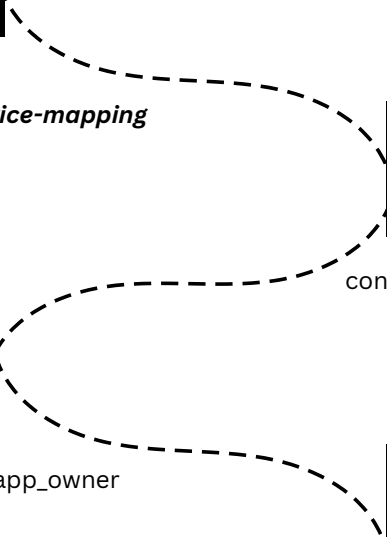

sm_admin, sm_user, sm_app_owner

Install Mid Server

configure credentials for host
machine

Verify Service
Mapping Setup

check if host machine is getting
discovered
